Abstract: The development of a sensitive SO₂ QEPAS based sensor platform employing a 140 mW CW-DFB-QCL will be reported. A detection limit of 75 ppbv (3σ) was achieved with a 1-sec averaging time for the 1380.94 cm⁻¹ SO₂ absorption line.

Keywords: (140.5965) Semiconductor lasers, quantum cascade; (300.6340) Spectroscopy, infrared; (280.4788) Optical sensing and sensors.

1. Introduction

A sensitive, selective and portable gas sensor based on quartz-enhanced photoacoustic spectroscopy (QEPAS) employing a high power 7.25 μm CW-DFB-QCL was developed for detecting SO₂ at ppbv concentration levels, suitable for environmental and industrial monitoring. SO₂ is a major air pollutant that is mainly released to the atmosphere by industrial combustion processes as well as fuel-based transport activities. SO₂ becomes toxic when its concentration exceeds 1 ppmv in ambient air [1]. In this work the influence of the H₂O presence in the sample gas mixture on the SO₂ sensor performance was investigated.

2. Quartz-enhanced photoacoustic spectroscopy (QEPAS)

QEPAS is a sensitive technique that allows performing measurement of trace gases in an ultra-small absorption detection module (ADM) with a total effective sample volume of a few mm³ [2]. The technique is based on the use of a 32.768 Hz quartz tuning fork (QTF) as a sharply resonant transducer for acoustic waves, which are induced in an absorbing gas by modulated optical radiation. The QTF is a piezoelectric element which converts its deformation by pressure waves into separation of electrical charges that can be measured as a voltage. An enhancement of the QEPAS signal can be achieved when two metallic tubes acting as a micro-resonator (mR) are added to the QTF sensor architecture. Moreover, for slow relaxing molecules, blending the gas mixture with water vapor, which is an efficient catalyst for V-T relaxation processes in the gas phase, can improve the detected QEPAS signal [3].

3. SO₂ QEPAS sensor architecture and performance

The QEPAS based gas sensor architecture is depicted in Fig.1. It employs a CW-DFB-QCL (Hamamatsu, L10195-7253H) as mid-IR light source. An anti-reflection coated aspheric collimating lens (Black Diamond™, f=3.05 mm) was used to collimate the laser beam. The laser beam quality was improved by implementing a spatial filter consisting of a plano-convex CaF₂ lens (f=25 mm) and a 300 μm pinhole. The QEPAS ADM consists of the QTF and the mR placed into a gas cell. A reference cell filled with 0.5 % of SO₂ in N₂ at 133 mbar and a pyroelectric detector located after the ADM were used as a reference channel in order to lock the laser frequency to the center of the selected SO₂ absorption line. The sensor platform is based on 2f wavelength-modulation spectroscopy (WMS) and QEPAS detection.

In order to implement the 2f-WM technique the DFB-QCL emission wavelength was tuned across the SO₂ absorption line centered at 1380.94 cm⁻¹ by applying a ramp to the laser current and modulating it sinusoidally at half of the QTF resonance frequency \(f_{\text{mod}}=f/2=16,384\); Hz. Once the optical energy is absorbed by the gas, the acoustic wave is generated and detected by the QTF. The induced QTF piezoelectric signal was enhanced by an ultra-low noise trans-impedance amplifier (TA) with a 10 MΩ feedback resistor. The amplified QTF signal was demodulated at \(f_0\), using an internal lock-in amplifier with a time constant set to 1 sec.

The presence of H₂O vapor influences the QEPAS response to SO₂ by enhancing the vibrational translational (V-T) energy transfer rate and thus increasing the photoacoustic signal. The optimum working pressure and modulation depth (MD) for dry SO₂ and for moisturized SO₂ (absolute humidity \(AH=2.3\) %) gas mixture was found to be 175 mbar and 9 mA, and 100 mbar and 6 mA, respectively. Fig. 2 shows a QEPAS spectrum of 10 ppm dry and moisturized SO₂ gas mixture. In order to investigate the dependence of H₂O on the response of the QEPAS
based SO₂ sensor the amplitudes of the 2f signals were acquired as a function of the H₂O concentration (p=100 mbar, MD=6 mA). The results demonstrated as an inset to Fig. 2 show that ~3.1 times improvement of the QEPAS signal was observed when the absolute humidity of analyzed gas mixture is 2.3 %. To lock the laser frequency to the center of the SO₂ absorption line in order to perform long term measurements a pyroelectric detector signal, demodulated by a lock-in amplifier at 3f, was employed. Fig. 3 shows an example of 2f WM QEPAS signals acquired at different concentration levels of dry SO₂ gas.

To investigate the sensitivity and linear response of the QEPAS sensor quantitative measurements of SO₂ were performed using a dry and moisturized SO₂ gas mixture. Different SO₂ concentration levels within the range of 0 to 10 ppm were achieved by diluting 50 ppm SO₂:N₂ calibration mixtures. The inset in Fig. 3 shows the linear response of the QEPAS sensor for different SO₂ concentrations for dry and moisturized gas at optimum sensor operating conditions in each case. The noise level was determined from the baseline recorded for the ADM filled with nitrogen. Good linearity between signals amplitude and SO₂ concentrations was observed for the QEPAS based sensor (dry gas: R²=0.9998, humidified gas: R²=0.9996). The determined QEPAS detection limit (3σ) is 75 ppbv for dry and 110 ppbv for moisturized SO₂ gas, respectively.
